#### Module 2: Introduction to Statistics

Niko Kaciroti, Ph.D. BIOINF 525 Module 2: W17 University of Michigan

## **Course Info**

#### Instructor

- Niko Kaciroti: <u>nicola@umich.edu</u>
  - Office: 300 N. Ingalls Bldg, 10-floor, #1027NW
  - Office hours: Friday 11:00pm to 12:00pm or by appointment
- Teaching Assistant
  - Lauren Jepsen: ljepsen@umich.edu
    - Office hours: Monday 12:00pm-1:00pm, Palmer 2065
- Data from TROPHY Study will be used for the class
  - Feasibility of treating prehypertension with an angiotensin-receptor blocker. New England Journal of Medicine. 2006; 354:1685-97.
- Grading
  - Homework
    - Students may form study groups to discuss class notes and homework assignments but must hand in their own work

# Торіс

- Probability distributions
- Quantifying central values and variability in the data
  - Mean, SD, Quartiles, Inter Quartile Range (IQR)
- Graphical display of data
  - Histograms, Boxplot
- Normal distribution
  - Q-Q Plots for Normality
  - Shapiro Wilks Test for Normality
  - Features of normal distribution/Central limit theorem (CLT)
- Other commonly used distribution
  - T-distribution,  $\chi^2$  distribution, **F** distribution

## **Statistical Programs**

- Some commonly used statistical programs:
  - SAS
  - SPSS
  - Stata
  - R/Rstudio
- R is an open source program, and will be used in the lab. It is available for downloaded at: <u>http://cran.r-project.org/</u> Rstudio at: <u>http://www.rstudio.com/ide/download/</u>
- Reference Book : *The R Book* 2<sup>nd</sup> edition by Michael J. Crawley

## Variable Types

- Discrete variables (or categorical data)
  - May take values as an integer or belong to a set number of categories
    - ✓ # Number of sunny days in January (0,1,2,...,31)
    - ✓ Gender (0="Female", 1="Male")
    - ✓ Race (1="White", 2="Black", 3="Asian", 4="Others")
- Continuous variables
  - May take any real value within a defined range
    - ✓ Height/Weight (6.11ft,/191.12lbs)
    - ✓ Blood Pressure (100.12mmHg)

## **Randomness and Probability**

- The concepts of randomness and probability are central to the field of statistics
- Most experiments are not perfectly reproducible: some experiments are more accurate, some are less
- We will outline the basic ideas of <u>probability distributions</u>, which are used to measure the degree of uncertainty and reproducibility

## **Probability Distributions**

 Probability distribution describes how data points are distributed. That is, what is the likelihood (or relative frequency) that a certain value occurs

- It is a mathematical <u>function</u> that *assigns* some probability to each of the possible outcome values of a random variable (X)<sup>+</sup>
  - Probability mass function (**pmf**): Is used for discrete variables
  - Probability density function (**pdf**): Is used for continuous variables

<sup>+</sup>X is a random variable if it can take <u>different</u> values, each with some probability.

- E.g., X indicates the outcome of tossing a coin (Tail/Head).

## **PMF for Discrete Variables**

- Pmf is a function that gives the probability that X equals to some value k, Pr(X=k).
  - E.g. Tossing a coin, the pmf is:
     *Pr*(X=Tail)=p=0.5

Pr(X=Head)=1-p=0.5

Rolling a dice, the pmf is:

*Pr(X=k)=p<sub>k</sub>=1/6* for k=1,2,...,6.

- Sum of all probabilities must be 1:

$$\sum_{k=1}^{n} Pr(X=k) = 1$$

## **PDF for Continuous Variables**

• The probability density function f(x) is a bit more complicated when x is continuous. It is defined as the limit when  $\delta x \rightarrow 0$  of :  $Pr(x \le X < x + \delta x) / \delta x = f(x)$ 

Here  $Pr(x \le X < x + \delta x)$  is the probability that X lies between x and  $x + \delta x$  where  $\delta x$  is small

 Another useful function describing the distribution is the Cumulative Density Function (CDF), which gives the probability that X is less than or equal to x:

$$F(x)=P(X \le x)=\int_{-\infty}^{x} f(x)dx$$

# Why It's Important to Learn About Different Distributions?

- It is necessary to decide which are the appropriate:
  - Descriptive measures (to best analyze/present the data)
  - Statistical test(s) when testing hypothesis
- Helps in deciding whether to transform your data
  - Does the data have characteristics that might make it inconsistent with the <u>assumptions</u> about the distributions used in a statistical test?

#### Commonly Used Distributions (Continuous Variables)

- **Normal** distribution with mean  $\mu$  and variance  $\sigma^2$
- *t* distribution with *k* degrees of freedom (aka Student's t distribution)
- **Chi-Square**  $(\chi^2)$  distribution with *k* degrees of freedom
- F distribution with (*n*, *m*) degrees of freedom
  - degrees of freedom (*df*) is the number of values in a statistics that are free to vary (not constrained).
  - *df*=n-#of constrains

Normal, t,  $\chi^2$ , and  $\mathscr{F}$  distributions are widely used for statistical testing (more on these later). These tests are derived based on normal distribution assumption, which makes the normal distribution vital to statistics.

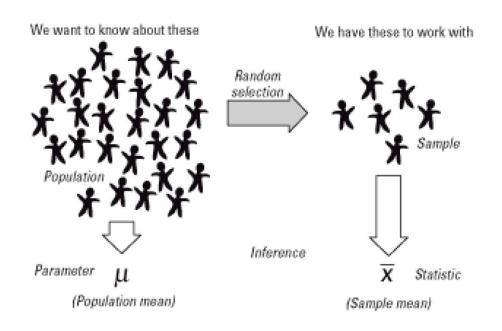

#### Commonly Used Distributions (Discrete Variables)

- Bernoulli distribution (Yes/No)
  - Tossing a coin, does it land "Tail": 1="Yes"/0="No")
- Binomial distribution (Number of successes in n trials)
  - Number of "tails" when tossing a coin n times (e.g. 5 times out of 10)
- Multinomial distribution (belonging to some categories)
  - Race 1=W, 2=B, 3=A, 4=Other
- Poisson distribution (count data: 0,1,2,....)
  - # of goals is a soccer game (0,1,2,....)
  - # of points in a football game???

# Торіс

- Other commonly used distribution
  - T-distribution,  $\chi^2$  distribution,  $\mathcal{F}$  distribution

# Sampling: What is the Difference Between a Sample and a Population?

- **Population** (or target population): It consists of all people or things that you want to describe (*N*)
  - *E.g.:* All males in graduate school at U of M in the academic year 2015-16
- **Sample**: Representative subset of the population. Taking a sample (at random) of *n* out of *N* individuals to estimate some characteristics (height) for the population
  - Sample: 50 males in graduate school at U of M in 2015 16

#### Sampling Example: Two samples of n=10 students

Sample 1	(height)	Sample 2 (height)
5.2		5.5
5.4		5.5
5.5		5.6
5.6		5.6
5.7		5.7
5.8		5.8
5.9		5.8
6.0		5.9
<u>6.1</u>		<u>5.9</u>

mean height5.75.7What is different between sample 1 and sample 2?

<sup>-</sup> Sample 2 is more homogenous. All heights are within 2 inches from the mean.

#### Quantifying Central Values and Variability in the Data Mean, Variance, Standard Deviation

Let  $x_1, x_2, \dots, x_n$ , be a random sample from a population.

• Mean, is defined as:

$$\overline{x} = \frac{\sum_{i=1}^{n} x_i}{n}$$

• Variance, is a measure of variability around the mean defined as the "average" of the squared deviations from the mean:

$$\widetilde{\sigma}^2 = \frac{\sum_{i=1}^n (x_i - \overline{x})^2}{n} \quad or \ s^2 = \frac{\sum_{i=1}^n (x_i - \overline{x})^2}{n-1}$$

• **Standard deviation (sd),** is square root of variance. It is measured in the same unit as the mean:

$$sd = \sqrt{s^2} = s$$

• Standard error (se), often is referred to as a measure of precision and is defined as:

$$se(\overline{x}) = \frac{s}{\sqrt{n}}$$

## Quintiles, Percentiles, Median, Quartiles, IQR

- *q***-Quintiles:** Are points that divide data into *q* equal subsets
- Percentiles (100-quintile): It is the value below which a certain percent of observations fall. *E.g.*, the 20<sup>th</sup> percentile is the value below which 20% of the observations are found
- Median: It is a value that splits the data into two equal parts (Median= 50 percentile, 2-quintile)
- Quartiles: Are values that divide the data into four equal parts Q1=25<sup>th</sup> percentile, Q2=50<sup>th</sup> percentile (median),Q3=75<sup>th</sup> percentile
- Inter Quintile Range (IQR): IQR=Q3-Q1

## **Calculating Percentiles**

Data	Sorted			
(n=11)				
11	11	The $p^{th}$ percentile of <i>n</i> values is the $p^{nth}$ value in the sorted data (round to the nearest integer in the list 1,2,,n of order)		
35	12			
31	22 ← Q1			
24	24			
12	30			
57	<i>31</i> - Median/Q2	Median: $0.5*11=5.5$ (the 6 <sup>th</sup> ) $\rightarrow$ 31		
32	32	Q1: $0.25*11=2.75$ (the 3 <sup>rd</sup> ) $\rightarrow 22$		
30	35			
22	<i>44</i> ← Q3	Q3: $0.75*11=8.25 \text{ (the 8th)} \rightarrow 44$		
77	57	IQR = Q3-Q1: 44-22=22		
44	77			
Mean=32.3				
SD=18				

## **Calculating Percentiles**

(Not sensitive to outliers)

Data	Sorted		
(n=11)			
11	11	Would the mean or median change if	
35	12	there was a large outlier?	
31	22 ← Q1		
24	24	Median: $0.5*11=5.5$ (the 6 <sup>th</sup> ) $\rightarrow 31$	
12	30		
57	<i>31</i> ← Median/Q2	Q1: $0.25*11=2.75$ (the $3^{rd}$ ) $\rightarrow 22$	
32	32	Q3: $0.75^{*}11=8.25$ (the 8 <sup>th</sup> ) $\rightarrow 44$	
30	35		
22	44 ← Q3	IQR = Q3-Q1: 44-22=22	
77	57		
44	777		
Mean=32.3 (96.9)			
SD=18	(215.4)

  - T-distribution,  $\chi^2$  distribution,  $\mathcal{F}$  distribution

#### Graphical Display of Data

- A visual or graphical display of data is a useful tool for understanding and summarizing the data. It should <u>always</u> be the first step on statistical analysis.
  - It is very useful for data quality control, checking for errors, unusual values or outliers
  - It is also useful for understanding the distributions of the data, which will help in choosing the appropriate statistical models
- Two important graphical display of data are:
  - Histogram
  - Boxplot

### Histograms

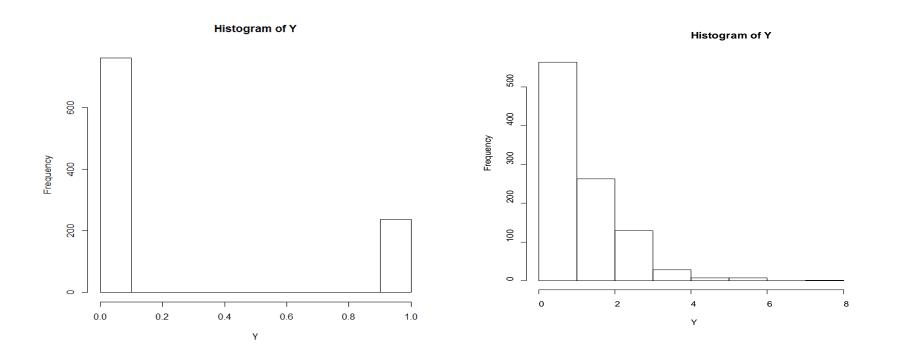

- A **histogram** is a graphical representation of the probability distribution for a given variable. It displays the frequencies of observations occurring in certain ranges of values
  - For discrete measures it shows the frequency of values in each category
  - For continuous measure it shows the frequency of values occurring in small intervals covering the whole range

#### Example: Histogram for Discrete Measures Simulated Data

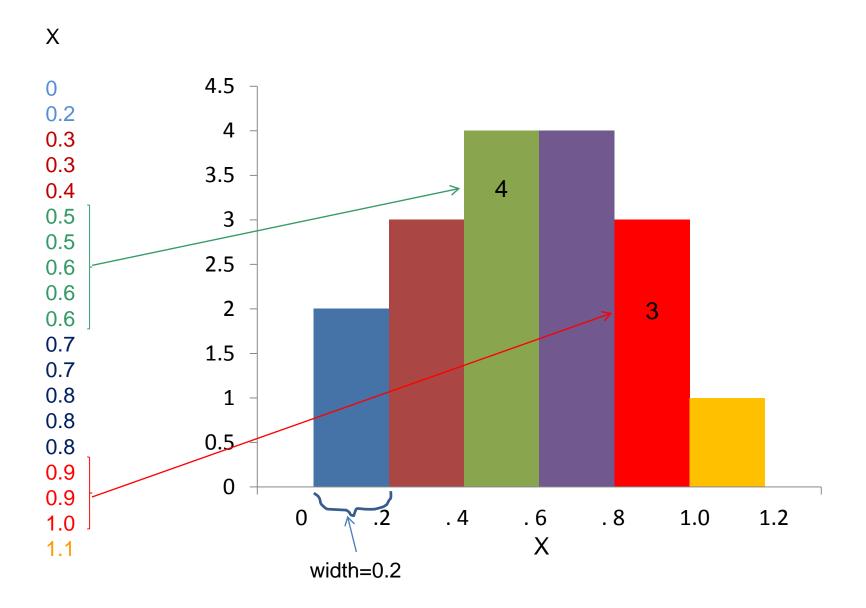

• In R

#### Y<-rbinom(1000,1,.25) hist(Y)

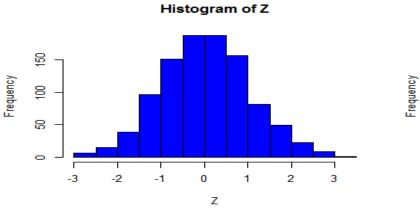

Y<-rpois(1000,1.5) hist(Y)

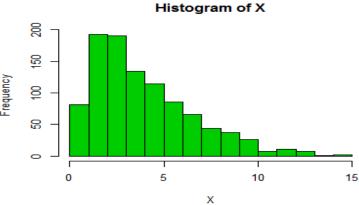

## Histogram for continuous Measures

#### Example: Histogram of continuous Measure Simulated Data

Histogram of Z

Density

What are some differences between blue and green histograms?

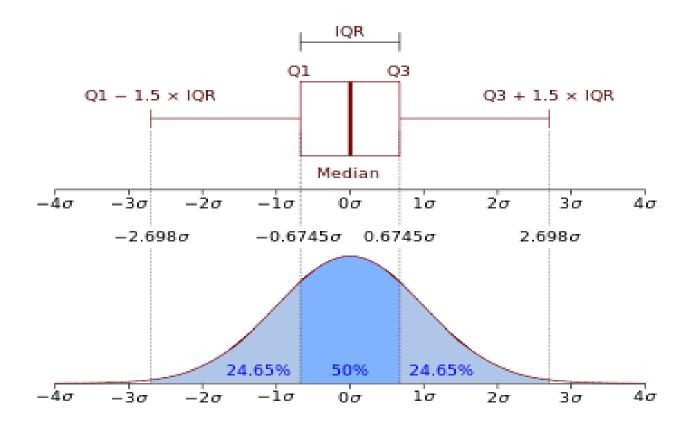

## **Boxplots**

- What is a boxplot
  - A **box plot** or **boxplot** (**box-and-whisker plot**) is a graphical tool
  - for conveying information on location, variation, and symmetry of the data.
  - It is also used for detecting and illustrating location and variation
     differences between two or more groups of data (side-by-side boxplot)

#### • Why it is useful?

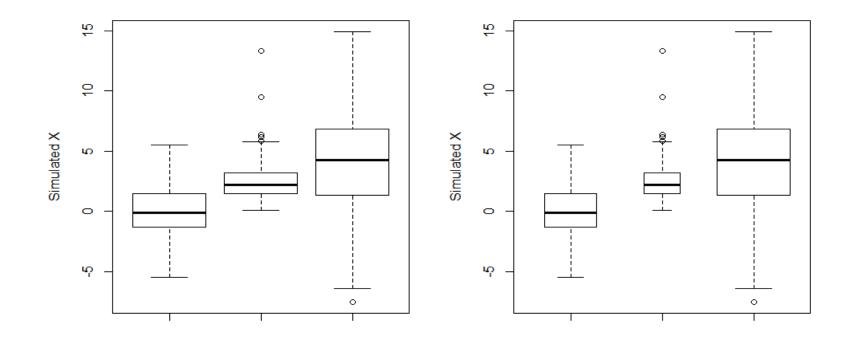

It is an efficient visual tool to summarize the main characteristics of the data: Mean/median, quintiles, spread, symmetry and outliers.

#### **Boxplot**

\*If the data are not normal the length of the whisker is up to the min/max value

#### Side-by-Side Boxplot Examples Using R (Simulated Data)

- In the second panel the larger the n the wider the box
- Which one has largest median? Smallest IQR?

# Торіс

- Probability distributions
- Quantifying central values and variability in the data
  - Mean, SD, Quartiles, Inter Quartile Range (IQR)
- Graphical display of data
  - Histograms, Boxplot
- Normal distribution
  - Q-Q Plots for Normality
  - Shapiro Wilks Test for Normality
  - Features of normal distribution/Central limit theorem (CLT)
- Other commonly used distribution
  - T-distribution,  $\chi^2$  distribution,  $\mathcal{F}$  distribution

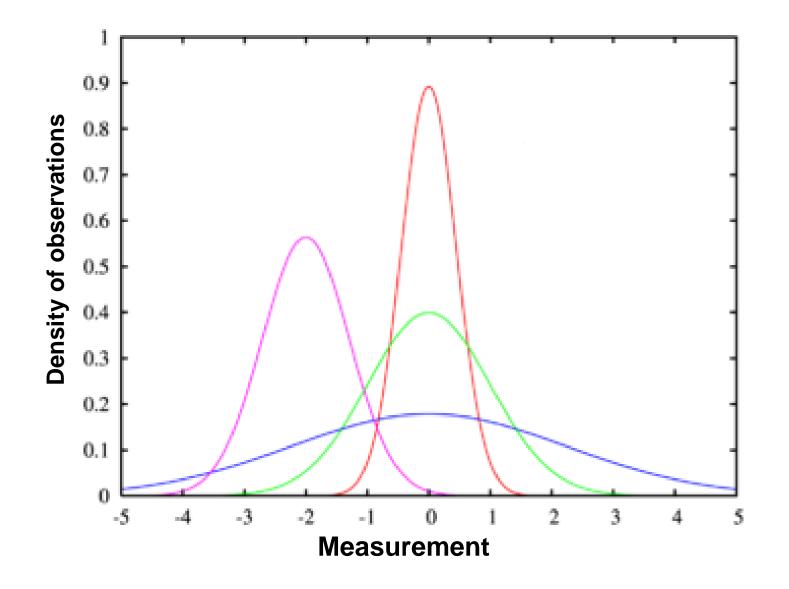

## **Normal Distribution**

- Normal distribution is the most used distribution (and a building block) in Statistics. It is used to describe and summarize real life data, and also to perform statistical testing
- If *X* is normally distributed we write:

 $X \sim N(\mu, \sigma^2)$ 

- "~" stands for 'is distributed as'
- $\mu$  is the mean parameter:  $\mu = \int x f(x) dx$
- $\sigma^2$  is the variance parameter:  $\sigma^2 = \int (x \mu)^2 f(x) dx$
- $-\sigma$  is standard deviation (SD)
- Pdf of X is:  $f(x;\mu,\sigma^2) = \frac{1}{\sigma\sqrt{2\pi}}e^{-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2}$

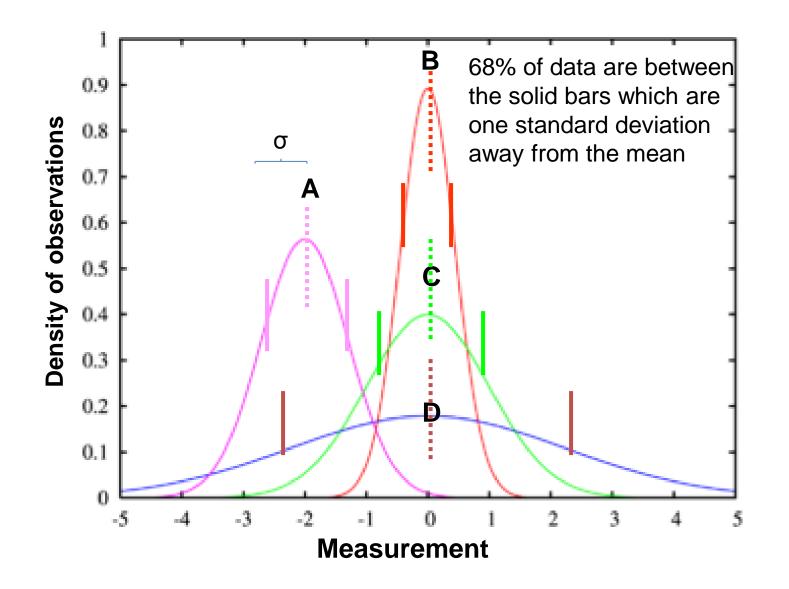

### **PDF of Normal Distributions**

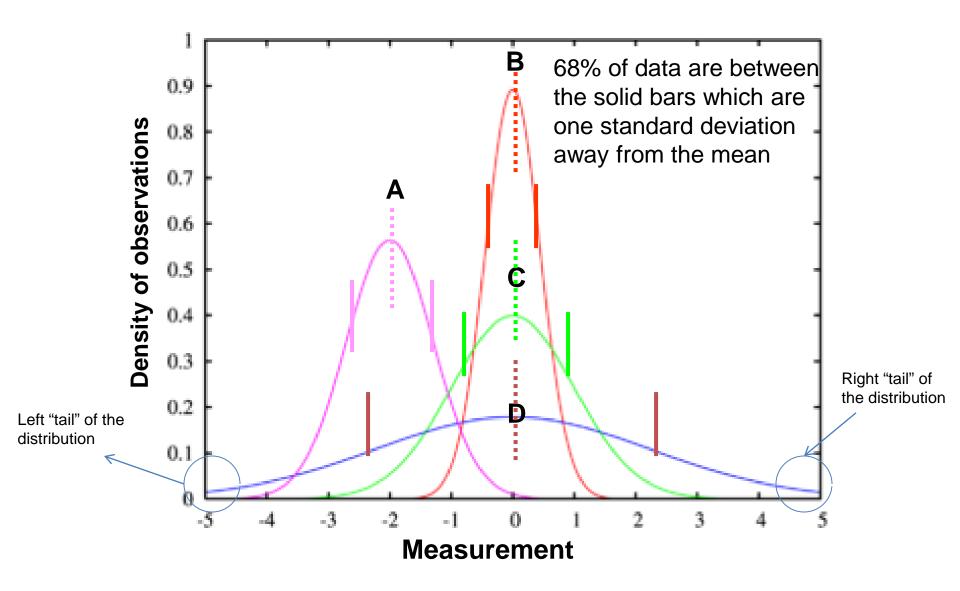

# Does the Mean (µ) Alone Define the Distribution?

## Standard Deviation (σ)

## Tail of the Distribution

## **Characteristics of Normal Distribution**

- It is a symmetrical bell-shaped curve
  - Most frequently occurring points around  $\mu$  (mean/median)
  - Points of inflection at  $\mu$   $\sigma$  (standard deviation) and  $\mu$  +  $\sigma$
  - 68/95/99 Rule
    - ✓ 68% of the data are within  $\mu$   $\sigma$  and  $\mu$  +  $\sigma$

 $P(\mu - \sigma < X < \mu + \sigma) \approx .68$ 

✓ 95% of the data are within  $\mu$  - 2 $\sigma$  and  $\mu$  + 2 $\sigma$ 

 $P(\mu - 1.96\sigma < X < \mu + 1.96\sigma) = .95$ 

 $\checkmark\,$  99% of the data are within  $\,\mu$  - 3 $\sigma$  and  $\mu$  + 3 $\sigma$ 

 $P(\mu - 3\sigma < X < \mu + 3\sigma) \approx .99$ 

Symmetric to the mean

✓ Skewness=0 (Left and right "tail" of the distribution are the same)

#### **Outliers for Normal Distribution**

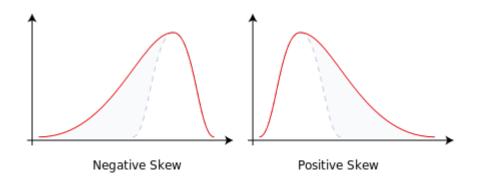

Mild outliers: < Q1 - 1.5\*IQR but > Q1 - 3\*IQR > Q3 + 1.5\*IQR but < Q3 + 3\*IQR

Extreme outliers <Q1 - 3\*IQR or >Q3 + 3\*IQR

# **Skewness Coefficient**

 Skewness is a measure of symmetry. A simple measure of Skewness is: Skewness=(mean-median)/sd

Why it is useful: If skewness is not 0, it indicates that the data are not normally distributed and a transformation may be needed.

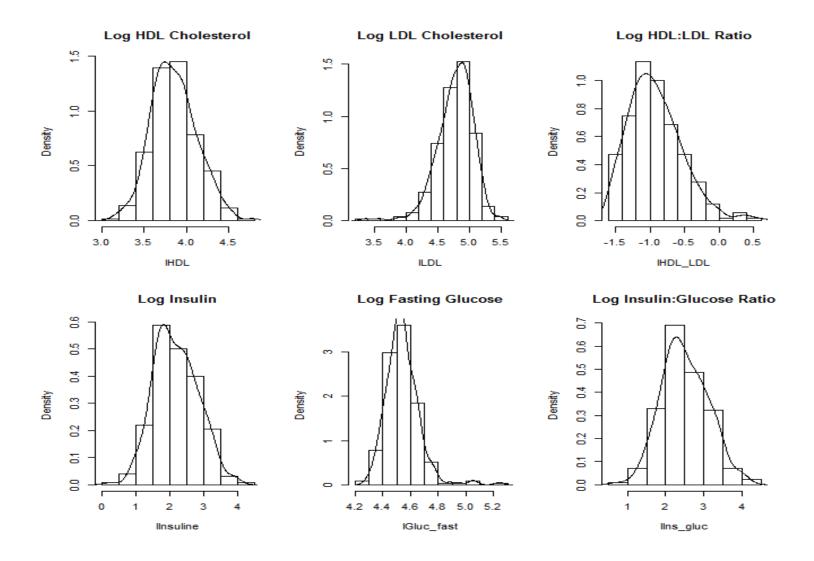

# Physiological Distributions

(Data from TROPHY Study\*)

\*Feasibility of treating prehypertension with an angiotensin-receptor blocker. *New England Journal of Medicine*. 2006; 354:1685-97.

### Log-transform Physiological Distributions

# Which of These Samples Might Have a Normal Distribution?

- A. Height of 50 males in graduate school at U of M in February 2016
   ✓ Yes.
- B. Household income of 10,000 randomly chosen people in the US
  - x No. Skeweness > 0 due to few high earners can stretch the tail to the right.

# **Testing for Normality**

- Plot to "test" for normality
  - Histograms: Bell shape, symmetry
  - Boxplot: Symmetry, outliers
  - Q-Q plot (Quantile-Quantile Plot)

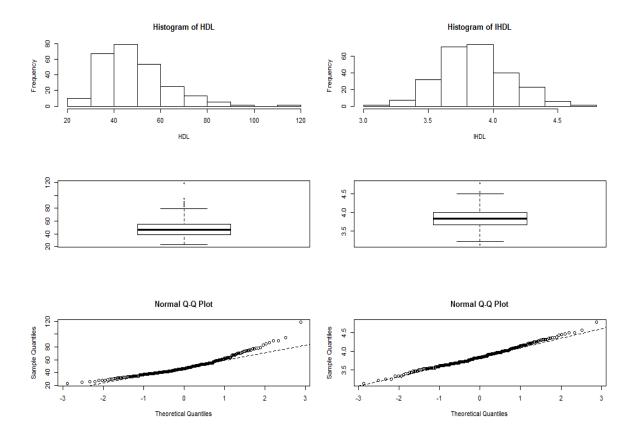

The simplest visual test of normality is the 'q-q plot'. This plots the quantiles of the observed data against the quantiles from a normal distribution.

If the data are normally distributed then the q-q plot will follow a straight line. Departures from normality show up as various sorts of non-linearity (e.g. S-shapes or banana shapes).

#### • Shapiro-Wilks test

Formal statistical test for normality

#### Plots to Test for Normality (TROPHY data)

# **Shapiro Wilks for Normality**

 Shapiro Wilks test is used to formally test for normality In R: shapiro.test(HDL) shapiro.test(IHDL)

Shapiro-Wilk normality test data: HDL W = 0.9305, **p-value = 1.394e-09** 

```
data: IHDL
W = 0.9926, p-value = 0.2322
```

• Conclusion:

If p-value < .05, then reject the hypothesis that data are normal

# **Shapiro Wilks for Normality**

 Shapiro Wilks test is used to formally test for normality In R: shapiro.test(HDL) shapiro.test(IHDL)

Shapiro-Wilk normality test

data: HDL

data: IHDL

W = 0.9926, **p-value = 0.2322**  $\longrightarrow$  No evidence that Log-HDL is not normal

• Conclusion:

If <u>p-value < .05</u>, then reject the hypothesis that data are normal

# Linear Transformation of Normally Distributed Random Variables are Normally Distributed

1. If X, is a normal random variables, with means  $\mu$ , and standard deviations  $\sigma$ , then the linear transformed variable will also be normally distributed

$$aX + b \sim N(a\mu + b, a^2\sigma^2)$$

2. If  $X_1$ ,  $X_2$  are two independent normal random variables, with means  $\mu_1$ ,  $\mu_2$  and standard deviations  $\sigma_1$ ,  $\sigma_2$ , then their linear combination will also be normally distributed

$$a_1X_1 + a_2X_2 \sim N(a_1\mu_1 + a_2\mu_2, a_1^2\sigma_1^2 + a_2^2\sigma_2^2)$$

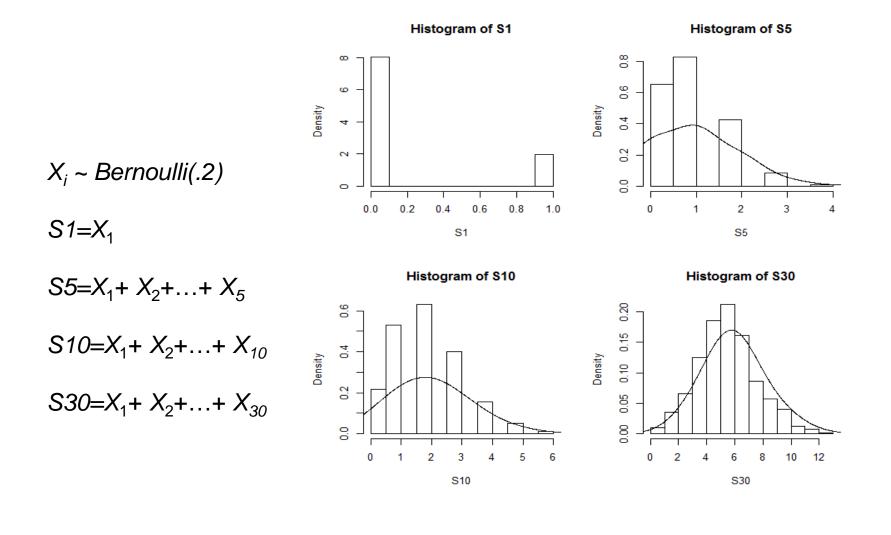

# Central Limit Theorem (CLT)

• If,  $x_1, x_2, ..., x_n$  is a sequence of independent identically distributed random variables, each having mean  $\mu$  and variance  $\sigma^2$ , then the CLT states that as the size (*n*) of the sample gets large, the distribution of  $\bar{x}$ , (or  $\sum_i x_i$ ) becomes normally distributed with E(Y)=  $\mu$ , Var(Y)= $\frac{\sigma^2}{n}$ .

$$\bar{x} \xrightarrow{d} N(\mu, \frac{\sigma^2}{n})$$
 or  $\sum_i x_i = \xrightarrow{d} N(n\mu, n\sigma^2)$ 

• Why is CLT important: If *n* is fairly large (*n* > 30), then following CLT one can implement statistical tests related to the  $\bar{x}$  (or  $\sum_i x_i$ ) that are based on normal distributed theory even if  $x_i$  are not normally distributed.

#### Illustration of Center Limit Theorem Using R (Simulated data in R)

### Application of CLT: 95% Confidence Intervals

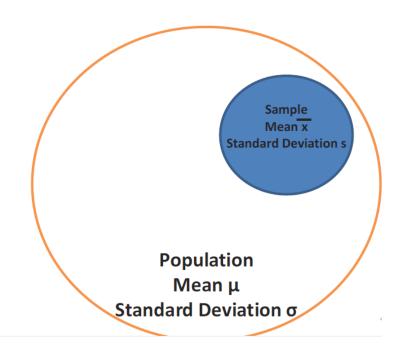

• From CLT: 
$$\overline{x} \xrightarrow{d} N(\mu, \frac{\sigma^2}{n})$$
 then (from 68/95/99 rule)  
 $Pr[\mu - 1.96 * \sigma/\sqrt{n} < \overline{x} < \mu + 1.96 * \sigma/\sqrt{n}] = 0.95$   
or  
 $Pr[\overline{x} - 1.96 * se(\overline{x}) < \mu < \overline{x} + 1.96 * se(\overline{x})] = 0.95$   
where  $se(\overline{x})$  is an estimate for  $\sigma/\sqrt{n}$ .

- $[\overline{x} 1.96*se(\overline{x}), \overline{x} + 1.96*se(\overline{x})]$  is referred as the 95%Confidebce Interval (95%CI) for  $\mu$
- More general: If  $\hat{\beta}$  is an estimate for  $\beta$  then:  $[\hat{\beta} - 1.96 * se(\hat{\beta}), \hat{\beta} + 1.96 * se(\hat{\beta})]$  is the 95%CI for  $\beta$
- Why are Confidence Intervals (CI) important?

### CI are Important When Making Inferences About a Population Based on a Sample

• Statistical Inference: Drawing conclusion based on data. Estimating the characteristics or properties of a population derived from the analysis of a sample drawn from it.

- What do  $\overline{x}$  and s tell us about  $\mu$  and  $\sigma$ ?

# How Close are Sample Values to Population Values?

Depends on Sampling Variability

The observed sample mean will vary The distribution of the sample mean is from sample to sample centered on the population mean sample size =10 sample size =1000 μ μ x =The spread of the distribution of the x = 3sample mean depends on the SD of the population and on the sample  $\overline{x} = 3$ size: x = $SE = \frac{SD}{\sqrt{n}}$  $\overline{x} = 1$ 

Confidence intervals are used to indicate the reliability of an estimate

  - Features of normal distribution/Central limit theorem (CLT)
- Other commonly used distribution
  - T-distribution,  $\chi^2$  distribution,  $\mathcal{F}$  distribution

# **T-distribution**

 Let, x<sub>1</sub>,x<sub>2</sub>,...,x<sub>n</sub>, be independently normally distributed with mean 0 and sampling variance s. Then the t-distribution is derive as:

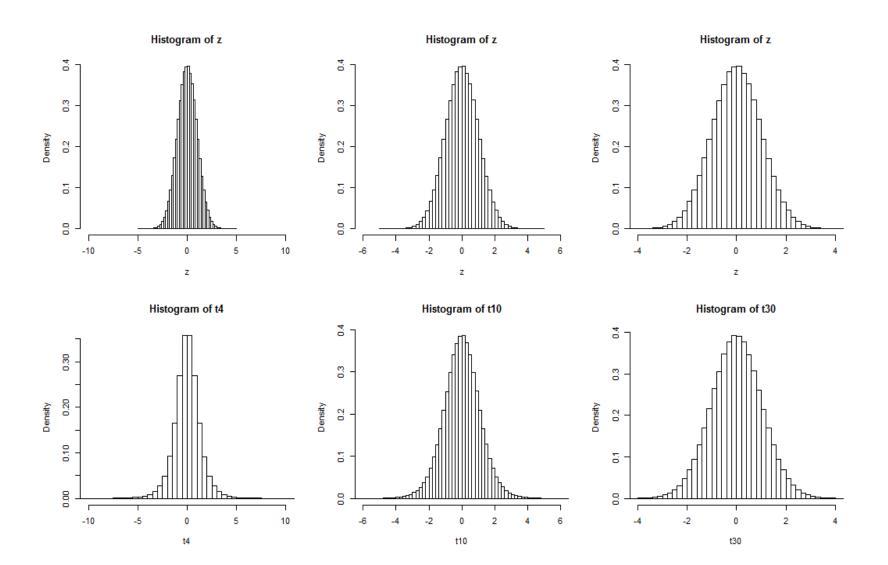

$$t_{n-1} = \frac{\overline{x}}{s/\sqrt{n}} = \frac{\overline{x}}{se(\overline{x})}$$

- The t distribution is very similar to the normal distribution except that, for small samples it has longer tails. As the sample size gets large, the t distribution approaches the normal distribution
- In many applications we will modify/transform the data to implement the t-distribution. In other words, we will convert something unknown into something whose properties are well established (t-distribution). E.g. if x<sub>1</sub>,x<sub>2</sub>,...,x<sub>n</sub> has mean μ then

$$t_{n-1} = \frac{\overline{x} - \mu}{s/\sqrt{n}}$$

# **Illustration of T-distribution**

(Simulated Data in R)

# Statistical Tests using T-distribution

- T-distribution and t-test (or Student's t-test)
  - One sample t-test,
  - Two sample t-test
  - Paired t-test

# $\chi^2$ distribution

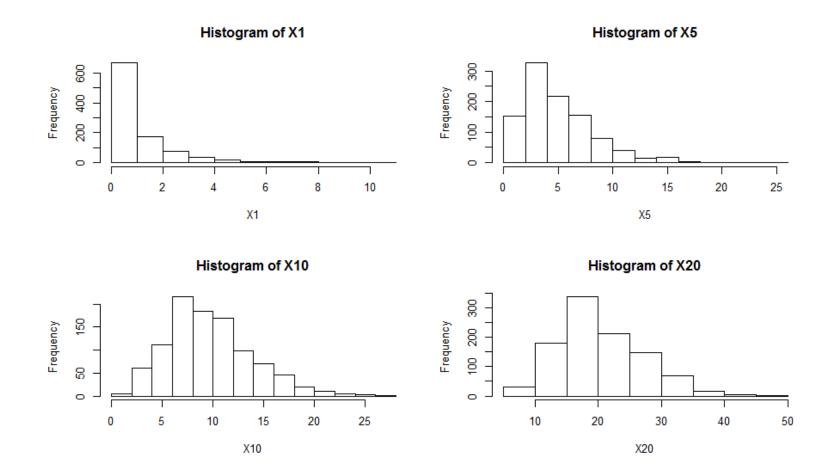

• If,  $Z_1, Z_2, ..., Z_k$  have a standard normal distribution ( $\mu$  =0,  $\sigma$  =1) then

$$X = \sum_{i=1}^{k} Z_i^2 \sim \chi_k^2$$

has a Chi-Square distribution with *k* degrees of freedom.

- The mean is: E(X)=k
- The variance is: Var(X)=2k
- $\chi^2$  distribution is used in  $\chi^2$ -test, most notably for categorical data analysis.

# $\chi^2$ distribution

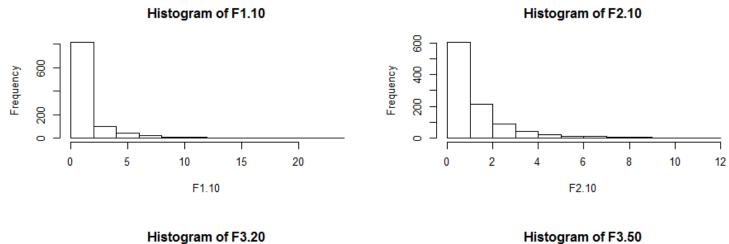

# **F** distribution

 If χ<sub>n</sub><sup>2</sup> and χ<sub>m</sub><sup>2</sup> are independent following Chi-Square distribution with *n* and *m* degrees of freedom, then their scaled ratio has an F distribution with (*n*, *m*) degrees of freedom:

$$\mathcal{F}_{n,m} = \frac{\chi_n^2/n}{\chi_m^2/m}$$

 F distribution is used in the F-test, most notably regression analysis or the analysis of variance

### **F** distribution

Histogram of F3.50

# **Few Summary Points**

Probability distribution: It describes how the data are distributed, giving the likelihood that a certain value occurs

- Commonly used distributions:
  - Categorical data
    - Binomial distribution
    - Multinomial
    - Poisson

Continues data

- Normal
- t-distribution
- Chi-Square (χ<sup>2</sup>) distribution
- F distribution

# **Few Summary Points**

#### Graphics:

- Histogram  $\rightarrow$  Examine distribution of a random variable
- Boxplot  $\rightarrow$  Examine the symmetry, spread, outliers
- Side-by-side Boxplots  $\rightarrow$  Compare distributions (median/IQR)

#### Quantifying central points and variability:

- Mean  $\rightarrow$  Measure of center, sensitive to outliers
- Median  $\rightarrow$  Measure of center, not sensitive to outliers
- SD  $\rightarrow$  Measure of spread, sensitive to outliers
- IQR  $\rightarrow$  Measure of spread, not sensitive to outliers

# **Few Summary Points**

#### **Test for Normality:**
